ATLANTA 22, GEORGIA

Vol. 11, No. 13

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED MARCH 31, 1962

INFLUENZA - Vermont reports small outbreaks of influenza-like disease in the center of the State which began in the middle of March. No other significant outbreaks have been reported in the United States this week. South Dakota reports a single serologic titer rise, bringing the number of States confirming Influenza B to 41. Slightly above expected levels this week, pneumonia and influenza deaths reported by 108 United States cities exceed expected levels for the 13th consecutive week.

Further outbreaks of Influenza B have been reported in several additional areas outside the United States. In France, a limited outbreak has been reported in a military hospital in Brittany; in the Federal Republic of

Germany, a widespread epidemic was recorded in Hesse during January; in Canada, several limited outbreaks were reported in Quebec.

Extensive epidemics confirmed as due to influenza A₂ have been reported from Hungary and Korea. Both were associated with a high disease incidence.

POLIOMYELITIS - Three paralytic cases were reported this week; two from separate counties in Texas and one from Indiana. No concentration of cases to any localized geographic area is yet apparent. The total of paralytic cases reported during 1962 is 49. Comparable figures during the previous five years are as follows:

Table 1. CASES OF SPECIFIED NOTIFIABLE DISEASES: UNITED STATES

(Cumulative totals include revised and delayed reports through previous week)

Disease	13th Week			Cumulative

Polio (Cumulative Total) Through 13th Week
For Past Five Years

	1962	1961	1960	1959	1958
Total Cases	76	103	216	296	216
Paralytic	49	60	154	211	121

HEPATITIS — A continuing decline in hepatitis cases is noted this week. (See graph, page 98). In each of the regions, the total cases reported are below 1961 levels except for New England which shows a moderate increase over last year. Within this region, Maine, New Hampshire, and Massachusetts account for the increased number of cases.

EPIDEMIOLOGICAL REPORTS

Typhoid Fever Related to Raw Oyster Consumption — Southeastern U. S.

During the last three months of 1961, a series of six cases of typhoid fever occurred in Florida, Georgia and Alabama, which subsequent investigation linked to a common source. The first five occurred during the 17 day period, October 16 to November 1; the sixth case experienced onset of symptoms on December 19. All had consumed raw oysters during the appropriate incubation period. The oysters consumed by the first five cases appear to have been processed by a single oyster shucking plant in Florida; those consumed by the sixth case were taken from an oyster bed from which the processing plant also received oysters.

Cultures obtained from each of these six cases have grown *Salmonella typhosa*, phage type A. Bacteriologic studies carried out by the CDC Enteric Bacteriology Unit reveal that each possesses a peculiar insusceptibility to

an unadapted mutant of Vi phage II isolated previously at the CDC laboratory. (Except for strains associated with this outbreak all typhoid organisms of phage type A tested at CDC thus far have proven susceptible to this phage.)

The first of the cases (see table) occurred in the wife of the owner of the oyster processing plant. The patient, who worked as an oyster shucker became ill on October 16. A second case occurred on October 23 in a 35-year-old woman also employed as a shucker at this plant. Both of these women frequently consumed oysters raw while engaged in shucking operations. A third case occurred on October 30 in a 21-year-old Negro male, the brother-in-law of the maid, who works for the owners of the oyster plant. He is known to have frequently consumed food, including raw oysters, obtained from the owner's house.

Age	Sex	Date of Onset	Residence	Occupation
28	F	Oct. 16	Apalachicola, Fla.	Shucker, wife of owner
51	M	Oct. 20	Meigs, Ga.	Farmer
35	F	Oct. 23	Apalachicola, Fla.	Shucker
21	M	Oct. 30	Apalachicola, Fla.	Brother-in-law of maid for owner
10	M	Nov. 1	Phenix City, Ala.	Student
51	F	Dec. 19	Valparaiso, Fla.	Housewife

Since oysters from this shucking plant were known to have been shipped during this period primarily within Florida and to Georgia and North Carolina, all typhoid cases of phage type A in these States were intensively investigated by the respective State Health Department authorities and CDC epidemiologists. In Georgia, during the preceding six months, only one case known to have been caused by a phage type A strain was recorded. This occurred on October 20 in a 51-year-old white male farmer from Meigs, Georgia. The patient regularly consumed large quantities of raw oysters purchased from a grocery store

in Meigs. It was established that this store is supplied by a trucker who distributes oysters processed by the Florida shucking plant. A review of North Carolina typhoid cases revealed only one to be of phage type A. This occurred in a non-oyster consumer; the organism did not show the unique phage typing characteristics common to the other strains.

Investigation about this time of a reported focal outbreak of typhoid cases in Phenix City, Alabama, revealed one bacteriologically confirmed and several suspect cases. The confirmed case was in a ten-year-old white boy who became ill on November 1. He consumed oysters on-the-half-shell at two restaurants in Columbus, Georgia, on October 22. Both restaurants were supplied by a single distributor who retained no records of purchases or shipments. The bulk of the oysters he receives, however, derive from Florida and, from known distribution patterns, could have been obtained from the suspect oyster processing house.

Intensive investigations, both epidemiological and laboratory, were carried out by the Florida State Board of Health. These included the processing of over 1,500 cultures of case contacts and employees of oyster shucking houses plus cultures of oysters, bay water, drinking water and sewage. One specimen only revealed *S. typhosa*. This was from a previously unknown typhoid carrier, a 67-year-old oyster tonger who worked alone and sold oysters exclusively to the single processing plant involved. The organism isolated from him was phage type A and, like those from the cases, was uniquely insusceptible to the unadapted mutant Vi phage II.

Intensive investigation of all typhoid cases occurring since early 1961 was undertaken by the Florida State Board of Health but, until December, no additional related cases were discovered. On December 19, a 51-year-old white female whose home is in Valparaiso, Florida, developed an enteric illness later identified as typhoid fever. *S. typhi* were recovered from her stool. Phage test-

(Continued on page 104)

MORTALITY SUMMARY - TOTAL DEATHS REPORTED IN 108 CITIES

For the four-week period ending March 31, deaths from all causes remained well above expected levels. Excess mortality fluctuated (see table) during the period, but averaged 435 deaths per week. In the corresponding period of the 1960 Influenza A₂ epidemic, the average weekly excess mortality was 635 deaths.

TOTAL DEATHS RECORDED IN 108 UNITED STATES CITIES

^oCurrent Week Mortality for 108 Selected Cities

4(A) Total Mortality, all ages.....	12,059
4(B) Pneumonia-Influenza Deaths, all ages.....	571
4(C) Total Deaths under 1 Year of Age.....	757
4(D) Total Deaths, Persons 65 years and over.....	6,722

*Estimate - based on average percent of divisional total
Totals for previous weeks include reported corrections.

NOTE: All deaths by place of occurrence.

ing at CDC revealed it to have the same characteristics as those obtained from others in the outbreak. The woman had eaten raw oysters on the halfshell on December 5. The oysters were traced to their source, the same bay from which the other oysters derived. They had been harvested on either November 28, 29 or 30; the tonger collecting these oysters worked in the same portion of the bay covered by the proven typhoid carrier. No other relationship could be established between these oysters and the known carrier or the other five cases; further studies are still in progress.

The oyster processing plant was closed immediately after the initial case was recognized; oysters in distributional channels were confiscated.

Intensive investigations of the entire oyster industry in Florida have revealed no evidence of additional sources of contamination with enteric pathogens.

(Reported by Dr. James O Bond, Director, Bureau of Preventable Disease, Florida State Board of Health; Dr. W. J. Murphy, Director, Epidemiology Service, Georgia Department of Public Health; Dr. W.H.Y. Smith, Director, Preventable Diseases, Alabama State Department of Public Health; Dr. Jacob Koomen, Asst. Director, Division of Epidemiology, North Carolina State Board of Health; and the Staff of the Communicable Disease Center.)
